# Introduction: Recommender Systems

$$i_u^* = \arg \max_{i \in I} \text{utility}(u, i)$$

(Adomavicius & Tuzhilin 2005)

Predictions for you ↴	Your Ratings	Movie Information	Wish List
★★★★★	Not seen	<b>About a Boy (2002)</b> DVD, VHS, info   imdb Comedy, Drama	<input checked="" type="checkbox"/> 🍌
★★★★★	Not seen	<b>Chicago (2002)</b> info   imdb Comedy, Crime, Drama, Musical	<input checked="" type="checkbox"/> 🍌
★★★★★	Not seen	<b>And Your Mother Too (Y Tu Mamá También) (2001)</b> DVD, VHS, info   imdb Comedy, Drama, Romance	<input type="checkbox"/>
★★★★★	2.5 stars	<b>Monsoon Wedding (2001)</b> DVD, VHS, info   imdb Comedy, Romance	<input type="checkbox"/>
★★★★★	4.0 stars	<b>Talk to Her (Hable con Ella) (2002)</b> info   imdb Comedy, Drama, Romance	<input type="checkbox"/>

# Introduction: Recommender Systems

$$i_u^* = \arg \max_{i \in I} \text{utility}(u, i)$$

The screenshot shows a table with four columns: Predictions for you, Your Ratings, Movie Information, and Wish List. The 'Your Ratings' column has a dropdown menu open, showing options from 'Not seen' to '5.0 stars'. The '4.0 stars' option is selected. The table lists several movies, including 'About a Boy (2002)', 'Chicago (2002)', 'And Your Mother Too (Y Tu Mamá También) (2001)', 'Monsoon Wedding (2001)', and 'Talk to Her (Hable con Ella) (2002)'. Arrows from the equation point to the 'Your Ratings' column and the '4.0 stars' option.

Predictions for you	Your Ratings	Movie Information	Wish List

- Collaborative filtering (Adomavicius & Tuzhilin 2005)

$$\text{utility}(u, i) = k \sum_{v \in N(u)} \text{sim}(u, v) \times r_{v, i}$$

# Is similarity enough?

- No, we propose the following modification

$$\text{utility}(u, i) = k \sum_{v \in N(u)} \gamma(v) \text{sim}(u, v) \times r_{v, i}$$

- Related work:

- Experts (Amatriain et al. 2009)
- Power users (Lathia et al. 2008)
- Trust (Kwon et al. 2009, O'Donovan & Smyth 2005)
- Dealing with users with little overlapping
  - Significance weighting:  $n/50$  (Herlocker et al. 2002)
  - Confidence (Clements et al. 2007)

# Our approach

- Predict “neighbor performance”  $\gamma(\cdot)$
- Adaptation of query performance prediction techniques
  - User / item clarity
- Check predictive power
  - Correlation against “neighbor goodness”
- Enhance CF performance with dynamic weights on neighbors

# Performance prediction in IR

- Mostly addressed as query performance (Hauff et al. 2008)
- Query clarity (Cronen-Townsend et al. 2002)
  - Distance (relative entropy) between query and collection language models

$$\text{clarity}(q) = \sum_{w \in V} P(w|q) \log_2 \frac{P(w|q)}{P_{\text{coll}}(w)}$$

$$P(w|q) = \sum_{d \in R} P(w|d)P(d|q), \quad P(q|d) = \prod_{w_q \in q} P(w_q|d)$$

$$P(w|d) = \lambda P_{ml}(w|d) + (1 - \lambda) P_{\text{coll}}(w)$$

- Query clarity captures the (lack of) ambiguity in a query with respect to the collection
  - Queries whose likely relevant documents are a mix of disparate topics receive a lower score than those with a topically-coherent result set.
  - Strong correlation between query clarity and the performance (average precision) of the result set

# Predicting good neighbors

- User “clarity”, item “clarity”...?
- Many possible ways to map query clarity to elements in CF
- For instance, for user clarity:

$$\gamma(u) = \textit{clarity}(u) = \sum_{v \in U} p(v|u) \log_2 \frac{p(v|u)}{p_c(v)}$$
$$p(v|u) = \sum_{i: \textit{rat}(u,i) \neq \emptyset} p(v|i) p(i|u)$$
$$p_c(v) = \frac{1}{|U|}$$

# Evaluation

- Correlation between predictor and performance metric
  - How do we define the “performance” of a neighbor?
- Final performance improvements when dynamic weights are introduced
  - Metric: RMSE
- Dataset:
  - MovieLens (100K)
- Two variables:
  - Neighborhood size
  - Sparsity (number of available ratings)
- Baseline:
  - Standard user-based kNN CF with Pearson similarity

# Assessing predictive power

- A neighbor performance metric is needed
- Proposed approximation to “neighbor goodness”  
How does a user affect the total MAE of the system

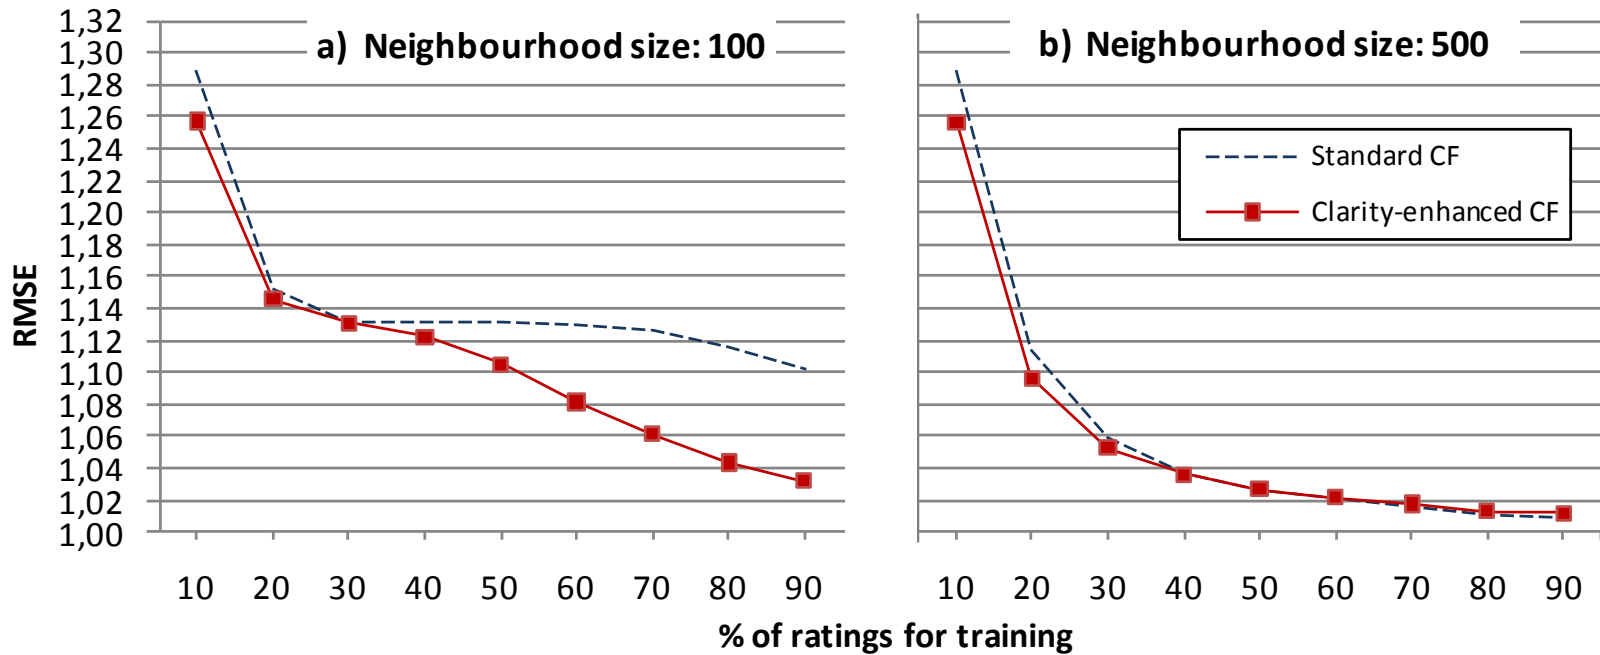

$NG(u) \sim$  “total MAE reduction by  $u$ ”  $\sim$  “MAE without  $u$ ” – “MAE with  $u$ ”

$$= \frac{1}{|R_{U-\{u\}}|} \sum_{v \in U-\{u\}} CE_{U-\{u\}}(v) - \frac{1}{|R_U|} \sum_{v \in U} CE_U(v)$$

$$CE_X(v) = \sum_{i:rat(v,i) \neq \emptyset} |\tilde{r}_X(v,i) - r(v,i)|$$

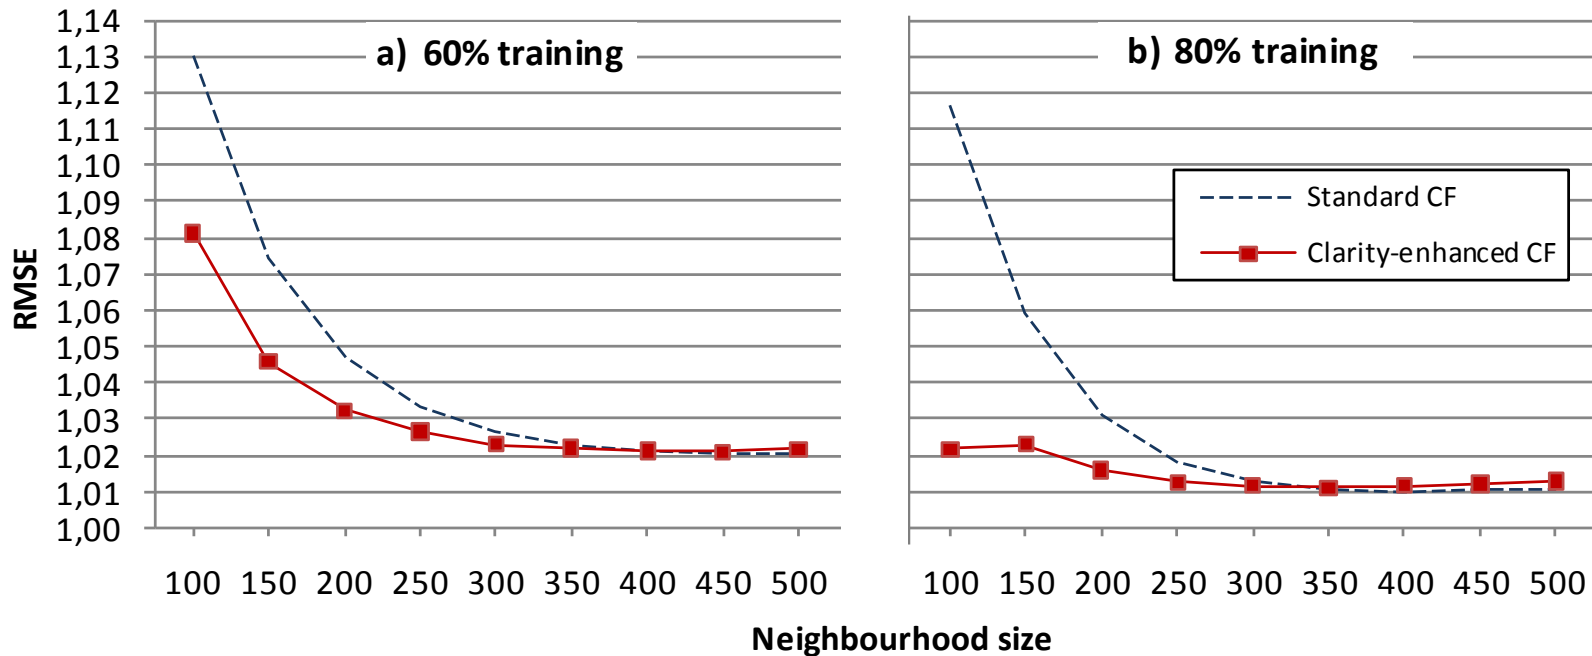

- Observed results
  - Pearson correlation of **0.18** (50% sparsity, p-value < 0.05)

# Dynamic neighbor weights in CF

Performance comparison for different rating density

# Dynamic neighbor weights in CF

Performance comparison for different neighbourhood sizes

# Conclusions

- Performance prediction for neighbor selection in CF
- Positive though moderate correlations values
  - Revise NG: is it an adequate metric?
  - Improve predictor
- Performance improvements using dynamic weights for neighbors
  - Higher difference for small neighborhoods

# Future work

- Alternative variants of clarity based predictor
  - Even  $\gamma(u, v, i, \dots)$
- Analysis of user performance metric
- Further comparison with other predictors: variance, social-based, time-based
- Predicting performance can be useful in many recommendation and personalization scenarios
  - Hybrid recommender systems, personalized IR, rank fusion

# Thank you
